

15.063 Communicating with Data Summer 2003

Solutions to Homework Assignment #2

Issued: Lecture 7. **Due: Lecture 11, before Lecture.**

The Exercises are from the book, *Data, Models, and Decisions: The Fundamentals of Management Science* by Dimitris Bertsimas and Robert M. Freund, Southwestern College Publishing, 2000.

Problem 2.22: Selling Umbrellas

Solution:

Let U_1 be the umbrellas sold at the department store, U_2 be the umbrellas sold at the outlet, and S be the total sales revenue. Then, $S = 17 U_1 + 9 U_2$. The expectation can be computed as:

$$E(S) = 17 \times 147.8 + 9 \times 63.2 = \$3,081,$$

and the variance as

$$\begin{aligned} \text{VAR}(S) &= 289 \text{VAR}(U_1) + 81 \text{VAR}(U_2) + 2 \times 17 \times 9 \times 51 \times 37 \times \text{Corr}(U_1, U_2) \\ &= 1,266,773, \end{aligned}$$

from where the standard deviation is $\sigma(S) = \$1,125.51$.

Problem 2.25: Defective Microchips

Solution:

Let A denote the event “the inspector accepts the microchip” and D denote the event “the microchip is defective”.

- We note that “the number of chips that are not defective” is a binomial distribution with $n=10$ and $p=0.95$. Then the desired answer is $(0.95)^{10} = 0.6$.
- Drawing a decision tree or a probability table (as you prefer), we can derive that $P(A) = P(A | D) P(D) + P(A | \text{not } D) P(\text{not } D) = 0.1 \times 0.05 + 1 \times 0.95 = 0.955$.
- As in part (a), “the number of accepted chips” is binomial with $n=10$ and $p=0.955$. Then, $p(\text{Accepts 9 out of 10}) = 10 \times (0.955)^9 \times 0.045 = 0.2973$.

(d) Using conditional probabilities, we derive that

$$P(\text{not } D \mid A) = 0.95 / 0.955 = 0.995.$$

(e) Now, we use conditional probabilities again:

$$\begin{aligned} p(\text{no defects } 10 \mid \text{accepts } 10) &= \\ &= p(\text{no defects } 10 \text{ and accepts } 10) / p(\text{accepts } 10) \\ &= p(\text{accepts } 10 \mid \text{no defects } 10) \times p(\text{no defects } 10) / p(\text{accepts } 10) \\ &= (0.995)^{10} \quad (\text{because } p(\text{accepts } 10 \mid \text{no defects } 10) = 1) \\ &= 0.95. \end{aligned}$$

Problem 2.27: Overbooking Flights

Solution:

Let X be the number of persons (out of 11) who show up. X is binomial with parameters $n = 11$ and $p = 0.8$.

(a) Using the binomial distribution, $P(X \leq 5) = 0.012$.

(b) $P(X = 10) = 11 \times (0.8)^{10} \times 0.2 = 0.236$.

(c) $E(X) = 11 \times 0.8 = 8.8$.

$$E(\text{Profit}) = 1200E(X) - 3000 p(X=11) = \$10,302.$$

To arrive to this answer you could have done a decision tree or a table with the profits and probabilities as well.

(d) Again, we have a binomial but now $n=10$. Then the expectation is

$$1200 \times 0.8 \times 10 = \$9,600.$$

(e) Yes, because if one person shows up, then it is very likely that his/her companions will also show up. Therefore, the event a person shows up is not independent of the event the next person shows up.

Problem 3.8: Pension Funds

Solution:

Let $T = 0.3 X + 0.7 Y$ denote the total annual return.

(a) $E(T) = E(0.3 X + 0.7 Y) = 0.3 \times 7 + 0.7 \times 13 = 11.2\%$.

(b) $\text{VAR}(T) = \text{VAR}(0.3 X + 0.7 Y) = 0.3^2 \times 2^2 + 0.7^2 \times 8^2 - 2 \times 0.3 \times 0.7 \times 2 \times 8 \times 0.4 = 29.03$,

$$\text{SD}(T) = \sqrt{29.03} = 5.4\%.$$

(c) T has a normal distribution (because it is the sum of two normals) with mean $\mu = 11.2\%$ and standard deviation $\sigma = 5.4\%$.

(d) Can be done using the normal distribution table or Excel:

$$\begin{aligned} P(10 < T < 15) &= P(-0.22 < Z < 0.70) \\ &= F(0.70) - F(-0.22) \\ &= 0.7580 - 0.4129 \\ &= 0.3451. \end{aligned}$$

Problem 3.11: MBA salaries

Solution:

Let A and B denote the initial salary and the bonus, respectively.

- (a) The compensation the first year is the salary plus the bonus. Then
 $E(A + B) = E(A) + E(B) = \$90,000 + \$25,000 = \$115,000$.
- (b) $\text{VAR}(A + B) = 20000^2 + 5000^2 = 425,000,000$ and $\text{SD}(A + B) = \$20,616$.
- (c) The compensation the second year is the salary with a 20% increase plus the bonus.
Then,
 $E(1.2 A + B) = 1.2 \times \$90,000 + \$25,000 = \$133,000$.
- (d) $\text{VAR}(1.2 A + B) = (1.2)^2 \times 20000^2 + 5000^2 = 601,000,000$ and
 $\text{SD}(1.2 A + B) = \$24,515$.
- (e) As A and B are normal, we know that the compensation the second year is normal too. Then,
 $p(1.2 A + B > \$140,000) = p(Z > 0.29) = 1 - P(Z < 0.29) = 1 - 0.6141 = 0.3859$.

Problem 3.20: Painting Cars

Solution:

- (a) $p(\text{Car returned}) = 1 - P(\text{Car is not defective}) = 1 - 0.80 \times 0.90 = 0.28$
(A car is not defective if both processes went OK. Note that the two processes are independent).
- (b) Let N denote the number of cars returned for rework. As N is a binomial RV,
 $E(N) = 1000 \times 0.28 = 280$ and
 $\text{SD}(N) = \sqrt{1000 \times 0.28 \times 0.72} = 14.2$.
- (c) Noticing that $np > 5$ and $n(1-p) > 5$, we can use the normal approximation to binomials.
Then, $P(N \leq 200) \approx P(Z < -5.63) = 0$.
- (d) X has a binomial distribution with parameters $n = 1000$ and $p = 0.20$. Y has a binomial distribution with parameters $n = 1000$ and $p = 0.10$.
- (e) As X and Y can be approximated by normals and the sum of normals is normal, X + Y can be approximated by a normal random variable with parameters
 $\mu = 1000 \times 0.20 + 1000 \times 0.10 = 300$ and standard deviation
 $\sigma = \sqrt{1000 \times 0.2 \times 0.8 + 1000 \times 0.1 \times 0.9} = 15.8$.
Using that X+Y is approximately normal, we can now use the table to compute
 $P(X + Y \leq 300) \approx P(Z < 0) = 0.5$.
