# Example: Titration of weak acid with strong base 25.0 mL of 0.10 M HCOOH with 0.15 M NaOH ( $K_a = 1.77 \times 10^{-4}$ for HCOOH)

#### 1. Volume = 0 mL of NaOH added

Before any NaOH is added, the problem is that of an ionization of a weak acid in water.

initial molarity HCOOH(aq)  $H_3O^+(aq) + HCO_2^-(aq)$  0.10 M 0 0 -x +x +xequilibrium molarity 0.10-x x x

 $K_a = 1.77 \text{ x } 10^{-4} = (x)^2 / (0.10 \text{ -} x) \sim = (x)^2 / 0.10$ 

x = 0.00421 (check 0.00421 is 4.2% of 0.10) okay

HCOOH (aq) + H<sub>2</sub>O (l)  $\longrightarrow$  H<sub>3</sub>O<sup>+</sup> (aq) + HCO<sub>2</sub><sup>-</sup> (aq)

pH = -log [0.00421] = 2.38 (to how many sig figs?)

## <u>2. $0 < V < V_{eq}$ </u>

In this range, the acid has been partly ionized by the strong base (buffering region).

<u>Calculate the pH of the solution resulting from the addition of 5.0 mL of 0.15 M NaOH</u>. Because OH<sup>-</sup> is a stronger base than  $HCO_2^-$ , it reacts almost completely with HCOOH. HCOOH (aq) + OH<sup>-</sup> (aq)  $\rightarrow$  H<sub>2</sub>O (l) + HCO<sub>2</sub><sup>-</sup> (aq) K>>1

Initial Moles

For HCOOH,  $(25.0 \times 10^{-3} \text{ L})(0.10\text{ M}) = 2.5 \times 10^{-3} \text{ moles}$ 

For OH<sup>-</sup>,  $(5.0 \times 10^{-3} \text{ L})(0.15 \text{ M}) = 0.75 \times 10^{-3} \text{ moles}$ 

Moles after Reaction

 $2.5 \times 10^{-3}$  moles - 0.75 x  $10^{-3}$  moles = 1.75 x  $10^{-3}$  moles of HCOOH left

0.75 x 10<sup>-3</sup> moles OH<sup>-</sup> produces \_\_\_\_\_ of HCO<sub>2</sub><sup>-</sup>

## <u>Molarity</u>

 $1.75 \times 10^{-3}$  moles of HCOOH/ (0.0250 + 0.0050 L) = 0.0583 M HCOOH 0.75 x  $10^{-3}$  moles of HCO<sub>2</sub><sup>-</sup>/ (0.0250 + 0.0050 L) = 0.0250 M HCO<sub>2</sub><sup>-</sup>

## Option 1

	HCOOH	$H_3O^+ + HCO_2^-$	
initial molarity	0.0583	0	0.0250
change in molarity	<u>-X</u>	+X	<u>+X</u>
equilibrium molarity	0.0583 -x	+X	0.0250 + x

 $K_{a} = 1.77 \text{ x } 10^{-4} = (0.0250 + \text{ x })(\text{x}) \text{ assume x is small } \sim = 0.0250 \text{ x}$  (0.0583 -x) 0.0583  $x = 4.13 \text{ x } 10^{-4}$ 

Check assumption:  $4.13 \times 10^{-4}$  is 1.65% of 0.025 and is 0.7% of 0.0583 okay pH =  $-\log [4.13 \times 10^{-4}] = 3.38$ 

### **Option 2**

 $pH \sim pK_a - \log ([HA]/[A^-])$  $pH \sim 3.75 - \log ([0.0583]/[0.0250]) = 3.75 - 0.368 = 3.38$ 

check assumption: for a pH of 3.38,  $[H_3O^+] = 4.2 \times 10^{-4}$  and that is <5% of 0.0583 and is <5% of

0.0250. Okay

If the 5% assumption is not valid, than option 1 must be used and

 $K_a = 1.77 \times 10^{-4} = (0.0250 + x)(x)/(0.0583 - x)$  can not be simplified.

Must solve by quadratic equation.

Note: when the volume of NaOH added is between 0 and the equivalence volume  $V_{eq}$ , the problems are similar to buffer problems. This region of the titration curve is called the "buffering region."

#### Half-equivalence point

When the volume of NaOH added is equal to half the equivalence volume,  $[HA] = [A^{-}]$ .

 $pH \sim= pK_a - \log ([HA]/[A^-])$   $pH \sim= pKa - \log (1)$  $pH \sim= pKa$ 

3.  $V = V_{eq}$ 

At the equivalence point, the amount of NaOH added is equal to the amount of HCOOH. The pH is not 7 as it is for a strong acid and a strong base. The pH is >7 when a weak acid is titrated with a strong base. The pH depends on the properties of the salt formed during the neutralization process. HCOOH and NaOH form NaHCO<sub>2</sub> and H<sub>2</sub>O. Na<sup>+</sup> has \_\_\_\_\_ on pH and HCO<sub>2</sub><sup>-</sup> is \_\_\_\_\_. Thus at the equivalence point, the pH is >7.

### Calculate the pH at the equivalence point

## Calculate total volume at equivalence point

moles of HCOOH =  $2.5 \times 10^{-3}$  moles = moles of HCO<sub>2</sub><sup>-</sup> formed = moles of OH<sup>-</sup> added

2.5 x  $10^{-3}$  moles of OH<sup>-</sup> x <u>1L</u> = 1.67 x  $10^{-2}$  L of NaOH added 0.15 mol Total volume = 0.0250 L + 0.0167 L = 0.0417 L

Molarity of HCO2-

 $2.5 \times 10^{-3}$  moles of HCO<sub>2</sub><sup>-/</sup> (0.0417 L) = 0.0600 M HCO<sub>2</sub><sup>-</sup>

This is an ionization of weak base in water problem.

 $HCO_{2}^{-}(aq) + H_{2}O(l)$  $\rightarrow$  HCOOH (aq) + OH<sup>-</sup> (aq)  $HCO_2^{-}(aq)$  $HCOOH(aq) + OH^{-}(aq)$ 0.0600 initial molarity 0 0 change in molarity +X -X +Xequilibrium molarity 0.0600 -x +X+ X

You can take it from here. Simplify if x is small compared to 0.0600 M. Calculate x, which is equal to  $[OH^-] = 1.83 \times 10^{-6}$  M. Then calculate pOH = 5.74. From pOH, calculate pH. pH = 8.26 (which is >7)

<u>4.</u>  $V > V_{eq}$ Beyond the equivalence point, NaOH is added to the solution of the conj. base HCO<sub>2</sub><sup>-</sup>. Since HCO<sub>2</sub><sup>-</sup> does not give rise to much OH<sup>-</sup> in solution (1.83 x 10<sup>-6</sup> M), the pOH and pH are determined by the amount of excess NaOH added. This problem is similar to a strong acid/strong base problem.

At 5.00 mL past the equivalence point:

 $0.00500 \text{ L} \ge 0.15 \text{ M} = 7.5 \ge 10^{-4} \text{ moles excess OH}^{-1}$ 

 $7.5 \times 10^{-4}$  moles OH<sup>-</sup> /(0.00500 L + 0.0250 L + 0.0167 L) = 0.016 M OH<sup>-</sup>

pOH = -log [0.16] = 1.79 pH = 12.21 Today's material

## OXIDATION/REDUCTION REACTIONS Guidelines for assigning oxidation numbers

1) In free elements, each atom has an oxidation number of zero. Example H<sub>2</sub>

2) For ions composed of only one atom the oxidation number is equal to the charge on the ion. Thus  $Li^{+1}$  has an oxidation number of +1. Group 1 and group 2 metals have oxidation numbers of +1 and +2, respectively. Aluminum has an oxidation number of +3 in all its compounds.

3) The oxidation number of oxygen in most compounds is -2. However, in peroxides such as  $H_2O_2$  and  $O_2^{-2}$ , oxygen has an oxidation state of -1.

4) The oxidation number of hydrogen is +1, except when it is bonded to metals in binary compounds, such as LiH, NaH, CaH<sub>2</sub>. In these cases, its oxidation number is -1.

5) F has an oxidation number of -1 in all its compounds. Other halogens (Cl, Br, and I) have negative oxidation numbers when they occur as halide ions in compounds (Ex. NaCl). However, when combined with oxygen (oxoacids), they have positive oxidation numbers (Ex. ClO<sup>-</sup>).

6) In a neutral molecule, the sum of the oxidation numbers of all the atoms must be zero. In a polyatomic ion, the sum of oxidation numbers of all the elements in the ion must be equal to the net charge of the ion. For example  $NH_4^+$ 

<u>H is</u>

N is

Sum is

7) Oxidation numbers do not have to be integers. For example, the oxidation number of oxygen in superoxide  $O_2^{-1}$  is \_\_\_\_\_

Examples 1 -

Li<sub>2</sub>O

HNO<sub>3</sub>

 $N_2O$ 

PCl<sub>5</sub>

<u>Definitions</u> Oxidation -Reduction -Oxidizing agent -Reducing agent -

#### **Disproportionation Reaction**

A reactant element in one oxidation state is both oxidized and reduced.

 $NaClO \Rightarrow NaClO_3 + NaCl$  in basic solution

Write the half reactions and determine the changes in oxidation state. Na<sup>+</sup> is a spectator ion so:

$$ClO^{-} \Rightarrow ClO_{3}^{-}$$

 $ClO^{-} \Rightarrow Cl^{-}$ 

Balancing Redox Reactions (Ch12.2) A. BALANCE IN ACIDIC SOLUTION

 $Fe^{2+} + Cr_2O_7^{2-} \Rightarrow Cr^{3+} + Fe^{3+}$ 

(1) Write two unbalanced half reactions for oxidized and reduced species.

 $\operatorname{Cr}_2 \operatorname{O}_7^{2-} \Rightarrow \operatorname{Cr}^{3+}$  $\operatorname{Fe}^{2+} \Rightarrow \operatorname{Fe}^{3+}$ 

(2) Insert coefficients to make the number of atoms of all elements except oxygen and hydrogen equal on the two sides of each equation.

$$\operatorname{Cr}_2 \operatorname{O}_7^{2-} \Rightarrow \operatorname{Cr}^{3+}$$
  
 $\operatorname{Fe}^{2+} \Rightarrow \operatorname{Fe}^{3+}$ 

(3) Add H<sub>2</sub>O to balance oxygen

$$\operatorname{Cr}_2 \operatorname{O}_7^{2-} \Rightarrow 2\operatorname{Cr}^{3+}$$
  
 $\operatorname{Fe}^{2+} \Rightarrow \operatorname{Fe}^{3+}$ 

(4) Balance hydrogen with H<sup>+</sup>

$$\operatorname{Cr}_{2}\operatorname{O}_{7}^{2-} \Rightarrow 2\operatorname{Cr}^{3+} + 7\operatorname{H}_{2}\operatorname{O}$$
  
 $\operatorname{Fe}^{2+} \Rightarrow \operatorname{Fe}^{3+}$ 

(5) Balance the charge by inserting electrons

$$14H^{+} + Cr_{2}O_{7}^{2-} \Rightarrow 2Cr^{3+} + 7H_{2}O$$
$$Fe^{2+} \Rightarrow Fe^{3+}$$

(6) Multiply the half reactions so that the number of electrons given off in the oxidation equals the number of electrons accepted in the reduction.

$$6e^{-} + 14H^{+} + Cr_2O_7^{2-} \implies 2Cr^{3+} + 7H_2O$$

$$Fe^{2+} \Rightarrow Fe^{3+} + e^{-1}$$

(7) Add half reaction, make appropriate cancellations.

 $6e^{-} + 14H^{+} + Cr_2O_7^{2-} + 6Fe^{2+} \Rightarrow 2Cr^{3+} + 7H_2O + 6Fe^{3+} + 6e^{-}$ 

B. BALANCE IN BASIC SOLUTION (Book has a different approach. You can use either.)

$$\operatorname{Fe}^{2+} + \operatorname{Cr}_2 \operatorname{O}_7^{2-} \Rightarrow \operatorname{Cr}^{3+} + \operatorname{Fe}^{3+}$$

Follow steps (1-7) to get your answer for acidic solution:

$$14H^{+} + Cr_2O_7^{2-} + 6Fe^{2+} \Rightarrow 2Cr^{3+} + 7H_2O + 6Fe^{3+}$$

(8) Then "adjust pH" by adding OH to both sides to neutralize H<sup>+</sup>.

$$14OH^{-} + 14H^{+} + Cr_2O_7^{2-} + 6Fe^{2+} \Rightarrow 2Cr^{3+} + 7H_2O + 6Fe^{3+} + 14OH^{-}$$
  
OR

$$14H_{2}O + Cr_{2}O_{7}^{2-} + 6Fe^{2+} \Rightarrow 2Cr^{3+} + 7H_{2}O + 6Fe^{3+} + 14OH^{-}$$
CANCEL  

$$7$$

$$14H_{2}O + Cr_{2}O_{7}^{2-} + 6Fe^{2+} \Rightarrow 2Cr^{3+} + 7H_{2}O + 6Fe^{3+} + 14OH^{-}$$
Thus:  $7H_{2}O + Cr_{2}O_{7}^{2-} + 6Fe^{2+} \Rightarrow 2Cr^{3+} + 6Fe^{3+} + 14OH^{-}$
